

Task 3 Importing Python modules and packages in python programming

PROBLEM 1

You are given a date. Your task is to find what the day is on that date.

Input Format

A single line of input containing the space separated month, day and year, respectively, in **MM DD YYYY** format.

Constraints

2000 < year < 3000

Output Format

Output the correct day in capital letters.

Sample Input

08 05 2015

Sample Output

WEDNESDAY

PROGRAM

```
import datetime
```

```
# Input
```

```
input_date = input("Enter the date in MM DD YYYY format: ")
```

```
month, day, year = map(int, input_date.split())
```

```
# Check if the year is within the specified constraints
```

```
if 2000 < year < 3000:
```

```
    x = datetime.datetime(year, month, day)    # Convert to datetime object
```

```
    day_name = x.strftime("%A").upper()        # Get and print the day in capital letters
```

```
    print(day_name)
```

```
else:
```

```
    print("Year is not within the specified constraints.")
```

OUTPUT

```
>>> .
= RESTART: E:/SUBJECT MATERIALS/veltech/subjects/WS 23-24/python/lab task/lab pr
actise/Task 3/3a.py
Enter the date in MM DD YYYY format: 01 27 2024
SATURDAY
>>> |           
```

Problem 2:

Given a number x, determine whether the given number is Armstrong number or not. A positive integer of n digits is called an Armstrong number of order n (order is number of digits).

Example:

$abcd... = \text{pow}(a,n) + \text{pow}(b,n) + \text{pow}(c,n) + \text{pow}(d,n) + \dots$

Input:

153

Output:

153 is an Armstrong number

$1*1*1 + 5*5*5 + 3*3*3 = 153$

PROGRAM

```
from math import pow
```

```
def compute_armstrong(x):
```

```
    n = len(str(x))
```

Converts the number `x` to a string. For

example, if `x` is 153, `str(x)` becomes the string "153".

```
    armstrong_sum = sum(pow(int(i), n) for i in str(x))
```

```
    return armstrong_sum == x
```

```
number = int(input("Enter a number: "))
```

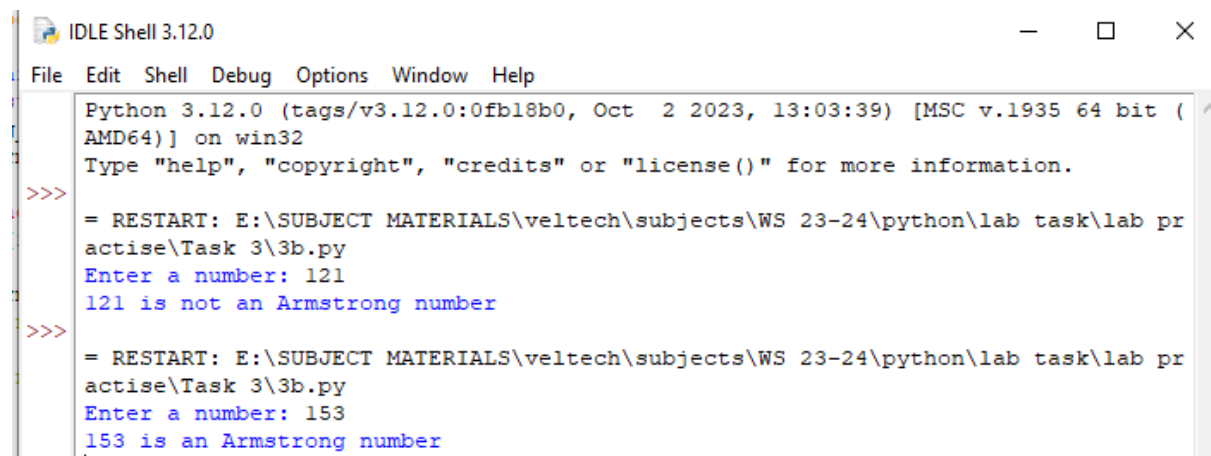

```
if compute_armstrong(number):
```

```
    print(f"{number} is an Armstrong number")
```

```
else:
```

```
    print(f"{number} is not an Armstrong number")
```

OUTPUT

```
IDLE Shell 3.12.0
File Edit Shell Debug Options Window Help
Python 3.12.0 (tags/v3.12.0:0fb18b0, Oct 2 2023, 13:03:39) [MSC v.1935 64 bit (AMD64)] on win32
Type "help", "copyright", "credits" or "license()" for more information.
>>>
= RESTART: E:\SUBJECT MATERIALS\veltech\subjects\WS 23-24\python\lab task\lab pr
actise\Task 3\3b.py
Enter a number: 121
121 is not an Armstrong number
>>>
= RESTART: E:\SUBJECT MATERIALS\veltech\subjects\WS 23-24\python\lab task\lab pr
actise\Task 3\3b.py
Enter a number: 153
153 is an Armstrong number
```

PROBLEM 3

K means clustering algorithm uses Euclidian distance measure. Write a Python program to compute Euclidian distance for two given points X (x1,x2) and Y (y1, y2)

Input: $X = (1,3)$ $Y = (2,3)$

Output:

1

PROGRAM:

euclidean distance module.py

```
import math
```

```
def edistance(x, y):
```

```
distance = math.sqrt((y[0] - x[0])**2 + (y[1] - x[1])**2)
```

```
return distance
```

3d.py

```
from euclidean_distance_module import edistance
```

$X = (1, 3)$ #Tuple

$$Y = (2, 3)$$

```
result = edistance(X, Y)
```

```
print("Euclidean distance between X and Y:", result)
```

This calculates the Euclidean distance between two points in a one-dimensional space. The distance formula is $\sqrt{(q[0] - p[0])^2}$, which results in $\sqrt{(1 - 3)^2} = \sqrt{4} = 2.0$. Therefore, the output of this part will be `2.0`.

This calculates the Euclidean distance between two points in a two-dimensional space. The distance formula is $\sqrt{(q[0] - p[0])^2 + (q[1] - p[1])^2}$, which results in $\sqrt{(6 - 3)^2 + (12 - 3)^2} = \sqrt{3^2 + 9^2} = \sqrt{9 + 81} = \sqrt{90}$. Therefore, the output of this part will be the square root of 90.

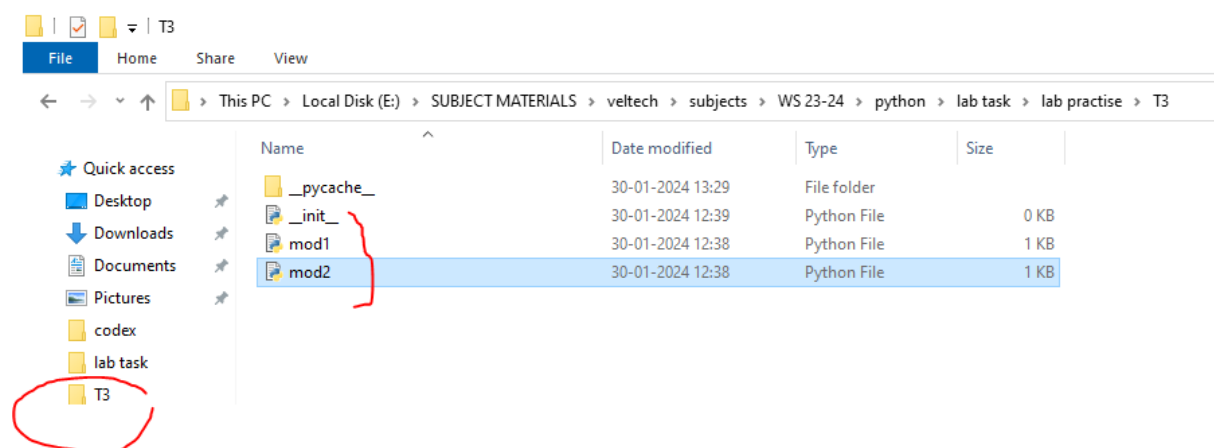

OUTPUT :

```
IDLE Shell 3.12.0
File Edit Shell Debug Options Window Help
Python 3.12.0 (tags/v3.12.0:0fb18b0, Oct 2 2023, 13:03:39) [MSC v.1935 64 bit (AMD64)] on win32

>>>
= RESTART: E:/SUBJECT MATERIALS/veltech/subjects/WS 23-24/python/lab task/lab practise/Task 3/3d.py
2.0
9.486832980505138
>>> |
```

PROBLEM 4:

You are working on a project where you need to create a Python package named "Greetings." This package should consist of **two modules**: one to display a welcome message, and another to perform addition.

SOLUTION :

PUT ALL THE BELOW FILES IN ONE FOLDER(PACKAGE) GIVE ANY FOLDER NAME..I Gave T3

__init__.py

//IT SHOULD BE AN EMPTY FILE

Mod1.py

```
def display():
    print("Hello World")
```

Mod2.py

```
def sum(a, b):
    return a+b
```

sample_task3.py

```
from T3 import mod1
```

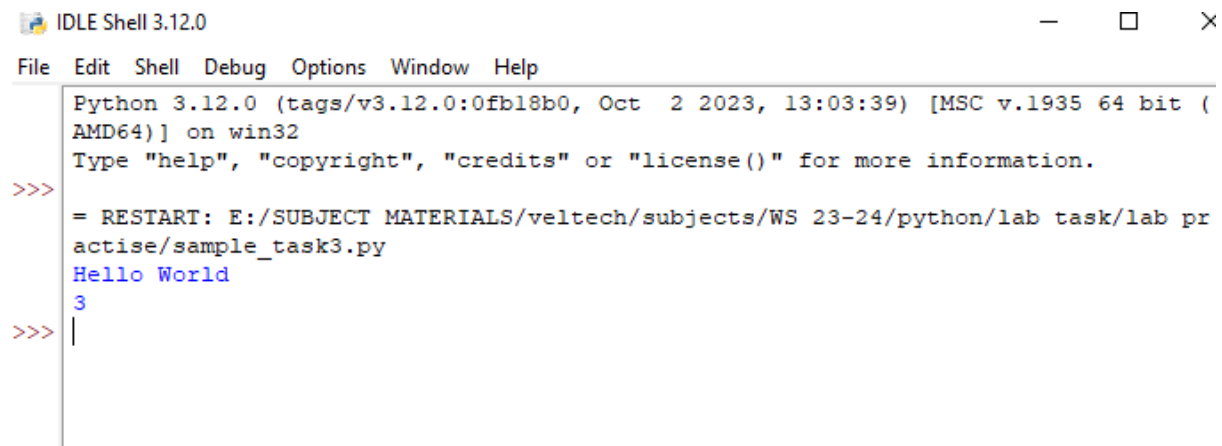

```
from T3 import mod2
```

```
mod1.display()

res = mod2.sum(1, 2)

print(res)
```

OUTPUT

Python 3.12.0 (tags/v3.12.0:0fbl8b0, Oct 2 2023, 13:03:39) [MSC v.1935 64 bit (AMD64)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

```
>>> = RESTART: E:/SUBJECT MATERIALS/veltech/subjects/WS 23-24/python/lab task/lab practise/sample_task3.py
Hello World
3
>>> |
```
